"Simple Procedure for the Determination of the Total 17,21-Dihydroxy-20-ketosteroid Content of Human Urine, Utilizing the Porter-Silber Color Reaction."

Budapest, Kiserletes Orvostudomány, Vol 14, No 5, Oct 62, pp 549-555.

Abstract: [Authors' Hungarian summary] For the determination of the total 17-hydroxycorticosteroid content of human urine a rapid and accurate method, also suitable for routine clinical testing, is described. To provide for more widespread use of the method, measurement with a simple Havesmann-type photometer is substituted for a spectrophotometric measurement. Authors find the method suitable for control of adrenocortical activity in clinical practice. Their normal values are: 18-50 year old women, 1.5-6.0 mg per day 18-50 year old men, 2.0-6.0 mg per day. "Chromatography of Steroids on Florisil Adsorption Columns."

Budapest, Kiserletes Orvostudomány, Vol XV, No 3, June 1963, pp 305-312.

Abstract: [Authors' German summary] Various steroids were chromatographed on "Nymco"-florisil adsorption columns by the authors. It was established that allopregnandiol and pregnandiol can be separated from pregnantriol and from the 17-hydroxycorticosteroids. The 17-ketosteroids can also be separated from pregnantriol and the 17-hydroxycorticosteroids. The chromatographic method allows a 100 per cent recovery of pregnandiol and the 17-ketosteroids from the florisil column. The yield is 78 per cent for pregnantriol and 75-85 per cent for the 17-hydroxycorticosteroids. The results indicate that the method can be used as a basis for a rapid separation and determination of the groups of steroids mentioned in biological materials, mainly urine. 4 Hungarian, 28 Western references.

Light absorption by complexes of aminobenzenesulfonic acids. Arpad Kiss and J. Faredin. *Acta Univ. Szeged., Chem. et Phys.* 2, 212-17 (1940) (in German).—Extinction curves of orthanilic and sulfanilic acids and of their complexes were detd. with mono-, bi-, and trivalent metal ions. Alkali metal complexes of both acids were dissolved in their aq. solns. Mg, Zn, Cd, Cu, Co, Ni, and Fe formed with sulfanilic acid complexes of the betaine type, whereas with orthanilic acid inner complex salts were produced. Both orthanilic and sulfanilic acids kept their selective absorptions in their complex salts unchanged. Their extinction values however were specifically changed by presence of colored metal ions. The complexes of orthanilic acids with the uncolored metal ions Mg, Zn, and Cd showed (as true complexes) a slight extinction at the borders of the visible area whereas the resp. complexes of sulfanilic acid were transparent in the same area.

TITLE: Development of an Electrolytic Method of Magnesium Recovery
(Razrabotka elektroliticheskogo sposoba polucheniya magniya)

PERIODICAL: V sb.: Legkiye metally. Nr 4. Leningrad 1957. pp 87-92

ABSTRACT: The history of the creation of Mg production in the USSR. The major efforts of the research and planning institutions and plants were directed toward improving the design of the cells and speeding the Mg electrolysis process. In recent years five anode cells of both top and side anode-insertion designs, operating at 60,000 amps, have been placed in operation. The working height of the anode has been increased from 80 to 100 cm. When the distance between poles is 8 cm, this does not result in any significant reduction in the current efficiency of Mg. These electrolysis procedures require 15 kWh/kg Mg when Mg chloride is subjected to electrolysis in a bath of optimal composition.

2211. The distribution of the muscular tone in different attitudes of the human body and with different movements of the upper limbs (Russian text) FARFEL M. N. Vrach. Delo 1956, 8 (839-842)

The muscle tone in 5 muscles of the upper limb and 3 of the lower limb, in 3 posi-

2211

tions of the body (standing, sitting and lying down), was measured with an electromyometer in 6 healthy persons. With different positions of the body the muscle tone was found to vary in its distribution and in the correlation of the distally and proximally placed antagonistic muscles. In the recumbent position, the highest tone was found in the anterior tibial muscle, in a sitting position, in the quadriceps and the triceps surae; in the standing position, the tone of the calf muscles increased further. With these successive changes in the positions of the body there was a progressive decrease in the tone of the upper limb. No asymmetry was observed in the tone of the homonymous muscles of the left and right limbs. The muscular contraction (work) of one upper limb is accompanied by an increase of tone in the opposite limb. Body posture and muscular activity are under the fine control of the central nervous system, regulating tone in the separate muscles as the result of the complex interaction of the differently stimulated centres of the motor analyser. Title : An Electromyographic Analysis of the Innervation of
Antagonistic Muscles under Conditions of Static Work.

Orig Pub : Tr. Leningr. sam.-gigien. med. in-ta i n.-i. detsk. or-
toped. in-ta, 1956, 29, 34-39

Abstract : Biopotentials of various muscles of the right arm were
recorded by an oscillograph. There was no electrical
activity (EA) in the antagonistic muscles of the right
arm when both arms were freely hanging. A change in
the arms' position (stretching forward on the level of
shoulders without any load) led to the appearance of

Card 1/3

USSR/Human and Animal Physiology - Neuro-Muscular Physiology. V-11

Abs Jour : Ref Zhur - Biol., No 1, 1958, 4355

biocurrents. The greatest EA was observed in the deltoid muscle. When static work was done by the right arm or by both arms (holding a load of 2 kg in each hand, the arm being stretched forward), the EA of all muscles was markedly increased (also the EA of the antagonistic muscles). When the left arm was doing static work, the EA of all the muscles of the right arm was increased, although this arm was not doing any work. The amplitude of the currents of the muscles of the right arm was increased by $1\frac{1}{2}$ - 2 times, as compared with the EA of the same muscles when the arms were freely stretched, without any load. The author noted a definite dependence of the state of the coordination centers of the muscles of one arm on the excitation processes taking place in the corresponding centers of the muscles of the other arm. An important role in the interaction

Potential of Muscles.

Orig Pub: Tr. Lening. San. gigien med. in-ta: n-i detsk. ortoped
in-ta, 1956, 29, 89-98.

Abstract: Local thermic action was applied to the skin of
rabbits and "spinal" frogs. The electrical potential
(P) was led from the muscle area subjected directly
to the action through silver needle electrodes to a
galvanometer. One electrode was inserted in the
muscle, the other one under the skin of the back.
Short (5 sec.) action of cold (0°C) had always a

Card : 1/2

USSR/Human and Animal Physiology. Neuro-Muscular Physiology.

T

Abs Jour: Ref Zhur-Biol., No 8, 1958, 36810.

lesser effect on P than the action of heat (40°C). Following denervation, these effects did not take place, which demonstrates the neuro-reflex mechanism of the subordinated manifestations. Under normal conditions of blood circulation, prolonged action of cold produced a more marked decrease of P, than under conditions of disturbed blood supply with intact innervation. Recurrent action (every 2 seconds, 10 times) were accompanied by maintenance of P at a certain determined level. Short single action on various areas of the skin produced a more marked fall of P, than action on one skin area only. These variations of P demonstrates that the phenomenon of summation is characteristic for the subordinating properties of the nervous centers.

Abs Jour : Ref Zhur - Biol., No 4, 1958, 18511

the brain. Heat applied to a deafferentated extremity did not give rise to visible changes in the electrical potential of the muscle under examination. During the first days of a rabbit's life, reflex changes in muscle potential in the presence of external influences are completely lacking. The formation of the subordination capacities of nervous centers depends on the time at which the eyes are opened.

TITLE: A device to measure the thickness of hot rolled metal

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 12, 1961, 13-14, abstract
12D92 (V sb. "Radioakt. izotopy i yadern. izlucheniya v nar. kh-vo
SSSR, vol. 3" Moscow, Gostoptekhnizdat, 1961, 205, 206)

TEXT: An instrument for measuring the thickness developed at TsNIIChM,
is based on the method of dynamic compensation. The device consists of a receiv-
ing unit, a container of the measuring source, an electric driver clamp, a feed
unit, a recording and an indicating unit. To control the operation of the device
a coarse-wedge sector is mounted. The device is employed in a thickness range
from 14 to 44 mm; it can however be designed for any range within 5 to 50 mm.
In the case of the given model the device is an indicating one. It is intended
to be incorporated into the programming unit, controlling the clamping screws of
the mill, as a correcting device on periodic-rolling mills, and as an indicator
in an automated reduction control system on continuous mills. The accuracy

Dětské Klin., Olomouc. "Subdurální hygrom při hnisavé meningitidě u dětí. Subdural hygroma in purulent meningitis in children PEDIAT.LISTY 1953, 6/4 (189 - 193)
Since antibiotics are used in purulent meningitis the authors tried to influence the sequelae of this disease. In 13 out of 26 children a subdural exudate was found and evacuated by puncture of the fontanelle, except in one patient, in whom surgery was necessary. The age of the children was up to 18 months.

2100. THE RELATION OF PATHOLOGICAL JAUNDICE OF THE NEWBORN TO KERNICTERUS - Vztah patologické novorozenecké žloutenky ke vzniku jádrového ikteru - Fargašová I., Dětská Klín. Lék. Fak. Palackého Univ., Olomouc - ACTA UNIV. PALAK. OLOMUCENSIS 1958, 15/14 (291-325) Graphs 14 Tables 9

The role of the serum bilirubin in the pathogenesis of kernicterus was studied in 2 groups: one of 102 children with haemolytic disease of the newborn and one of 32 mature and 111 premature children with pronounced physiological icterus. The influence of exchange transfusions on the bilirubin curve was studied. In 26 children with haemolytic disease of the newborn a study was also made of the influence of

the administration of ACTH on the serum bilirubin level. The findings can be summed up as follows: (1) The role of hyperbilirubinaemia in kernicterus can be demonstrated best of all in haemolytic disease of the newborn. Only concentrations of more than 25 mg. per 100 ml. are dangerous. Children with a bilirubin level of more than 30 mg. per 100 ml. are affected with kernicterus in more than 50% of the cases. Children with physiological icterus, even those prematurely born, are in much less danger from a high bilirubin level; term children only rarely develop kernicterus. (2) The danger to the central nervous system in haemolytic disease lasts certainly 4, perhaps 5 days. For children with physiological icterus the duration of the danger period could not be determined. No correlation could be demonstrated between the cerebral lesions and the duration of the influence of the dangerous serum bilirubin concentration. (3) From the fact that the incidence of kernicterus varies among cases with equally high serum bilirubin values, it can be concluded that it is not only the hyperbilirubinaemia which is responsible for the damage to the brain but that apart from the bilirubin other substances are involved, which are predominantly produced in the course of the haemolytic process and are probably concerned with the more general metabolic disturbance. (4) The quantity of blood used for the exchange transfusion, and the fall of the bilirubin level during the exchange have no constant correlation with the rise of the bilirubin curve, and it is therefore not possible to predict the duration of the effect of the exchange transfusion on the basis of these data. The principal factor in this connection is the activity of the disease, for which the child's age and the bilirubin level at the beginning of the exchange transfusion are indicative. The optimal quantity of blood for the exchange transfusion lies between 200 and 240 ml. per kg. body weight. This quantity of blood removes from the circulation so much bilirubin - and also of its source - that there is little danger of a rise to a dangerous level. (5) ACTH proved to be inefficacious in haemolytic disease of the newborn, even as an ancillary therapy after exchange transfusion: it prevents neither the dangerous rise of the bilirubin nor the damage to the central nervous system
